INTRODUCTION

The number of memory episodes increase with age. Yet, we are still able to retrieve relevant memories quickly.

We ask:

1. Does set-size affect long-term memory retrieval times?
2. Can different cues reduce memory retrieval times?

MAIN CONCLUSION

The set-size increases Long-Term Memory retrieval times. Additional cues can decrease retrieval times, but only if they are specific.

Experiment 1

Methods

Associative-learning phase

Participants learned lists of word pairs. Words were tested in a cued recall task. We manipulated: 1. Set size of the lists 2. Similarity of the word pairs

Distractor task

Cued recall phase

Model

Results

Effect of set size

Set size affects both retrieval times and accuracy.

Effect of similarity

Similarity between cues and targets improve retrieval times and accuracy.

Experiment 2

Methods

Learning phase

Results

Retrieval performance declines as the number of items associated with a semantic cue increases, even for a constant set size.
